FOREWORD

The efforts of many people were required to design and construct the magnetometer experiments and to process the resultant data without which this Interplanetary Magnetic Field Data Book could not have been generated. These include, at Goddard Space Flight Center, Dr. N. F. Ness and his colleagues during the years 1961-1975, including at different times Drs. D. H. Fairfield, R. P. Lepping, K. H. Schatten (now at Victoria University, New Zealand), and Y. C. Whang (permanently at Catholic University), and Messers. K. W. Behannon, D. R. Howell, J. L. Scheifele, J. B. Seek, and R. F. Thompson. These also include, at Imperial College, London, Dr. P. C. Hedgecock and his colleagues, Prof. H. Elliot, Dr. J. J. Quenby, and Mrs. A. Evans.

Dr. E. A. Scarzafava at the National Space Science Data Center (NSSDC) did the programming involved in the transition from experimenter-supplied tapes to the newly available composite tape and to the following listings and plots. Dr. R. H. Hilberg was instrumental in the regeneration of IMP 1 and IMP 3 hourly averages. Ms. L. Glicenstein and Mr. F. Richter provided editorial and graphic assistance, respectively.

To all these individuals we extend our thanks.

INTRODUCTION

Accurate measurements of the weak interplanetary magnetic field (IMF) beyond the terrestrial bow shock are among the more difficult studies in space physics to perform. Since the May 1965 launch of IMP 3 and for virtually a full solar cycle, IMF measurements have been made on a nearly continuous basis. A detailed history of interplanetary and non-interplanetary magnetic field measurements made through 1969 is found in Ness (1970).

The purpose of this report is to present an IMF data set that is uniform with respect to inclusion of cislunar IMF data only and yet which has as complete time coverage as presently possible over a full solar cycle. The report has been prepared for the convenience of investigators of macroscale phenomena in the interplanetary medium (sector structure, heliolatitude variations, solar cycle variations, etc.) and of other phenomena (e.g., ground level cosmic-ray events) for which knowledge of the IMF with hourly resolution is necessary. The report consists of listings and plots of cislunar hourly averaged IMF parameters over the period November 27, 1963, to May 17, 1974, and a discussion of the mutual consistency of the IMF data used herein. The magnetic tape from which the plots and listings were generated, which is available from the National Space Science Data Center (NSSDC), is also discussed.

THE EXPERIMENTS

The IMF data utilized in this report were produced by the fluxgate magnetometers flown on eight IMP and AIMP spacecraft by N. F. Ness and colleagues at Goddard Space Flight Center (GSFC) and by the HEOS 1 and HEOS 2 fluxgate magnetometers of P. C. Hedgecock and colleagues of Imperial College, London. Figure 1 indicates the individual spacecraft whose data were used (see Table 1 for spacecraft identifiers), the time period covered by each within the present data compilation, and the percent coverage per 27-day solar rotation interval yielded by the combined IMP/AIMP/HEOS data set*. There are data given for 52,929 individual hours between November 27, 1963, and May 17, 1974, in this composite data set. Of these hours, 51,714 occur after May 28, 1965. These figures represent about 58 and 66 percent coverages, respectively, for the indicated time periods.

*This combined data set constitutes a subset of the IMF data held at NSSDC. Also held at NSSDC are finer time scale data and data from other experiments and experimenters on both tape and microfilm. See the NSSDC data catalogs for details.

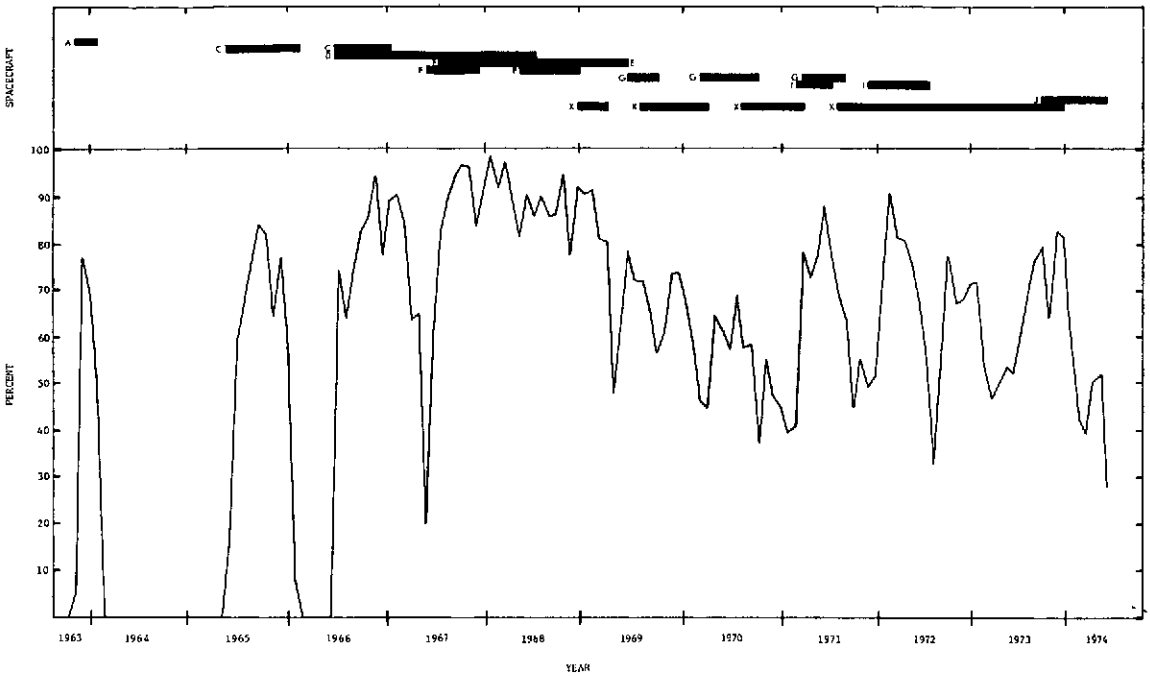

Figure 1. Percent coverage per 27-day interval in, and spacecraft contributing to, composite IMF data set.

The two main data gaps visible in Figure 1 occur between early 1964 and mid-1965 and during the first half of 1966. Few vector IMF data are available in cislunar space (well beyond the bow shock) for these periods, although the distant IMF was measured during parts of the first and second periods by Mariner 4 (Coleman et al, 1967) and by Pioneer 6 (Scearce et al, 1968; Ness and Ottens, 1971), respectively. Some useful cislunar IMF data were obtained by IMP 2 in late 1964, but due to the unexpectedly low spacecraft apogee (about 16 Earth radii) the quantity of this data was small (Fairfield and Ness, 1967).

Sources of additional cislunar hourly averaged IMF data, which will become available through NSSDC in the future, are: AIMP 1 from late 1968 into 1970 from C. P. Sonett; AIMP 2 from mid-1969 into 1972; IMP 5 for 1972; IMP 6 for 1973 and 1974; IMP 7 for late 1972 and early 1973; HEOS past 1973; IMP 8 past mid-1974. Some of this data will be used, when appropriate, to generate a supplement to the present volume to improve and extend the time coverage contained herein.

Tables 1 and 2 contain the salient features of the pertinent spacecraft and experiments. SC ID is the spacecraft identification used in the following data listings. For IMP and AIMP spacecraft, the values used correspond to prelaunch designations. Note that because on the experimenter-supplied tapes, HEOS 1 and HEOS 2 data are indistinguishable, a common SC ID is assigned.

APOGEE and PERIGEE are initial values for the geocentric spacecraft. For lunar orbiting AIMP 2, these and subsequent orbit parameters relate to the Moon's orbit about the Earth. (Most data taken in the geometric lunar shadow, which are affected by problems in field direction determination, have been excluded from this data compilation. However, apparent 11-hour periodicities found in the data between mid-1967 and mid-1969 could be due to the incomplete removal of lunar wake effects.) INCLIN is the geographic inclination. PERIOD (HR) and SPIN PERIOD (SEC) give the satellite orbital period about its parent body and the spacecraft spin period, respectively. B FIELD indicates the net spacecraft field at the sensor location. EXP OP DATES are the experiment operation dates between which most or all of the data for the experiment were obtained. Very limited data were obtained past the indicated end dates for IMP 1 and AIMP 2. Note that the HEOS 1 end date is the predicted spacecraft reentry date. It is hoped that IMP 8 will continue to acquire IMF data at least until the 1977-1978 period of the International Sun Earth Explorer (ISEE) mission launch.

In Table 2, NO. SENSORS indicates the number of independent fluxgate sensors. For cases of three sensors, the sensors were mutually orthogonal. For IMP 3, two sensors were flown but one malfunctioned shortly after launch. FLIP? indicates whether the sensors could be flipped. In the absence of the flip capability, sophisticated analyses have been used in sensor zero level determination, e.g., Hedgecock (1975B). UNCERT indicates the intrinsic digitization uncertainty associated with experiment and spacecraft telemetry systems and ground data processing. BANDPASS is the detector bandpass before onboard processing. SAMPL RTE gives the rate at which individual magnetic vectors are measured by the experiment, while FTS MAGN refers to the fine time scale of the field magnitudes from which hourly magnitudes were computed. That the product of these last two parameters is not unity for some spacecraft is discussed in the Data Processing section below. DATA USED refers to the earliest and latest IMF data contained in the listings and plots of this data compilation. The references cite those published papers in which instrument characteristics are most thoroughly discussed. For spacecraft launched through 1969, these references are well supplemented by Ness (1970) from whom much of the information of the present tables was taken.

DATA PROCESSING

In the normal flow of the experimenter's data processing for any given IMP or AIMP spacecraft, both hourly averaged magnetic field parameters and fine time scale plots are generated. The plots have been visually scanned (by D. H. Fairfield (primarily), R. P. Lepping, K. W. Behannon, and J. H. King) to identify time periods during which

the spacecraft was beyond the Earth's bow shock. The subset of hourly averaged data corresponding to these interplanetary intervals was then collected onto tape with the IMF hourly averages from the other IMP/AIMP spacecraft. This tape was used as input to the present data compilation.

A pair of tapes containing HEOS 1 and HEOS 2 IMF data was also used as input. These were provided by P. C. Hedgecock, who followed a procedure similar to that previously described in identifying interplanetary intervals and in generating and separating hourly averages.

From these two sets of input tapes, a merged tape was generated containing the following parameters: (1) time, (2) solar rotation number, (3) spacecraft position, (4) field magnitudes, (5) field latitude and longitude angles, (6) field Cartesian components, (7) standard deviations, (8) number of fine time scale points in hourly average, (9) solar latitude, and (10) a spacecraft identifier. These items are discussed individually below.

(1) Time - Year, day, and hour are given. The day number on the tape uses the convention that January 1 is day 0 but in the listings to follow, January 1 is day 1. Hourly averages are computed from the start of one hour to the next and are not centered on the hour.

(2) Solar rotation number - This number assumes the value 1783 on November 2, 1963, and increases by increments of one at 27-day intervals. This is the convention used on standard K_p diagrams.

(3) Spacecraft position - The geocentric distance and solar ecliptic Cartesian components of the position vector are given in Earth radii for the IMP and AIMP data only.

(4) Field magnitudes - The magnitude (B1), which results from hourly averaging fine time scale magnitudes, and the magnitude (B2) of the vector formed from hourly averaged Cartesian components of fine time scale field components are both given. The fine time scales used are indicated by the FTS MAGN in Table 2. For IMP 1 and IMP 3 data, only B2 values were available on the experimenter-supplied tape, so NSSDC personnel generated B1 values from an NSSDC-held tape data set containing 327-second field magnitudes.

Note from the SAMPL RTE column of Table 2 that the highest time resolution of the IMPs 1, 3, 6, and 8 data were not used in determining hourly averages. In particular for IMP 1 and IMP 3, the 327-second magnitudes used in hourly averaging were determined as the magnitudes of the vectors formed from 327-second components which were themselves obtained by averaging over the 20-second components.

Note that the fine time scales range from 1 second to 5.46 minutes. In the presence of significant directional fluctuations in the IMF on time scales shorter than 5 minutes, B1 values arising from 1-second magnitudes and those resulting from 5-minute magnitudes are not directly comparable. This point will recur in the Mutual Consistency section of this report.

(5) Field latitude and longitude angles - These angles are given in solar ecliptic coordinates and are determined from the hourly averaged Cartesian components of the field. (These angles, as determined by averaging over fine time scale angles, are available at NSSDC for HEOS on experimenter-supplied tapes.)

(6) Field Cartesian components - These are given in solar ecliptic coordinates and are determined from fine time scale components.

(7) Standard deviations - For IMP and AIMP data the root-mean-square standard deviations in the magnitude (for some spacecraft) and component averages are given. For HEOS records, the standard deviations in the magnitude average and angle averages are given. To have a consistent parameter for the IMP/AIMP data and HEOS data, we have defined

$$\sigma_{IMP} = \left[\sigma_{B_x}^2 + \sigma_{B_y}^2 + \sigma_{B_z}^2 \right]^{1/2},$$

$$\sigma_{HEOS} = \left[\sigma_B^2 + B^2 \sigma_\Theta^2 + B^2 \cos^2 \Theta \, \sigma_\phi^2 \right]^{1/2}.$$

Then we have taken $\sigma = \sigma_{IMP}$ for IMP and AIMP data and $\sigma = \sigma_{HEOS}$ for HEOS data. Here σ constitutes the consistent parameter that provides a measure of the total fluctuations, both in magnitude and direction, of the IMF within a given hour. It is this σ that is used in the subsequent data plots and listings.

(8) Number of fine time scale points in hourly average - At this point it is useful to note that for some spacecraft a time scale intermediate between that given in FTS MAGN (Table 2) and hourly values is involved. For example, for AIMP 1 and AIMP 2, 81.92-second sequence-average values, which were generated from 5.12-second values, were used in the generation of hourly averages. The only other such cases are IMPs 6 and 8 in which 15.36-second averaged data (obtained from 1.28-second data) were used in generating hourly averages. The "fine time scales" given in Table 2 refer to the finer time scale

since this gives a measure of the range of field direction fluctuation periods which cause B1 to differ from B2. On the other hand, the "number of fine time scale points in hourly average" given on the composite tape refers to the less-fine time scale points. Similarly the standard deviations are associated with the process of hour-averaging the less-fine time scale data.

(9) Solar latitude - This is the latitude of the Sun as given in a geomagnetic coordinate system for data records of IMPs 5, 6, and 8 only.

(10) Spacecraft identifier - This is as given in the first column in Table 1. For any one hour, data are given on the composite tape from one spacecraft only. For those hours when data from more than one spacecraft were available, the spacecraft was chosen that was used for the previous hour. If not available, the first spacecraft available (on an earlier tape with all data) for the hour was used. The only exception to these rules was if data from IMP 3 or AIMP 2 were selected, and other spacecraft were available, the first such other spacecraft was chosen. The rationale for this will be discussed in the Mutual Consistency section of this report.

This merged tape, written at 9 track, 800 bpi in binary on an IBM 360 computer, is available on request from NSSDC. It is intended that this tape will be updated as additional appropriate data become available. Since a listing of all the parameters on the tape would be prohibitively long, we have selected parameters to be listed and plotted on the following pages. The parameters listed for each hour are: time; field magnitude (B1) as determined from fine time scale magnitudes; field component perpendicular to the ecliptic; field latitude and longitude angles; the derived rms standard deviation parameter common to HEOS, IMP, and AIMP records; and the spacecraft identifier.

The subsequent plots contain the same parameters as the listings, except that neither the normal field component nor the spacecraft identifier is included in the plots. Much qualitative information, which would be conveyed by plots of the normal field component, is conveyed by the field latitude angle plot.

MUTUAL CONSISTENCY OF THE DATA

Any given IMF set has an intrinsic uncertainty associated with its "measured" field values. For most of the 10 data sets contributing to the present composite data set, the principal source of uncertainty is the digitization into a given number of bits of the magnetometer output voltage. These uncertainties are listed in Table 2.

Ideally, a composite data set consisting of two data sets each with an intrinsic uncertainty of 0.2 gamma should itself have an intrinsic uncertainty of about 0.2 gamma. To check this point and to quantify the confidence to be placed in various IMF parameters, the following mutual consistency study was performed. First, all the data was divided into quarters of a year (not by the calendar but by heliolatitude). For example, the quarter identified as quarter 1 of 1968 actually covers the period January 20-April 20, 1968, when the Earth and its orbiting spacecraft were at heliolatitudes between about -5 and -7.2 degrees. Twelve quarters were then selected as having many common hours of data coverage from some pair of spacecraft. For each of these quarters and for each spacecraft of the pair identified for that quarter, quarterly averages of the hourly field magnitudes, components, latitude and longitude angles, and standard deviations were determined using only hours common to both spacecraft. In addition, differences in each parameter between one spacecraft and the other were determined for each common hour and were averaged over the quarter. The rms standard deviations in these quarterly averaged differences were also determined. The cyclic longitude variable was handled in such a way that hourly differences were always less than 180 degrees. The main results of this common-hours comparison are shown in Table 3, where three successive rows relate to the comparison for one spacecraft pair and one quarter. The first row of each group gives the quarterly averages of the hourly values for one spacecraft of the pair. The second row gives the quarterly averages of the differences between hourly values for the two spacecraft. The third row gives the rms standard deviations in the averages of the second row. The units are gammas and degrees.

In addition to the common-hours comparison, averages for B and for B_z for each spacecraft over the portions of the spacecraft lives used in this report have been computed (see DATA USED fields of Table 2). Similar averages over 1967-1968 for the AIMP 1 and AIMP 2 data of C. P. Sonett have also been computed. These averages, in gammas, are given in Table 4.

TABLE 3

IMP 8	Ness	2,122	6.0	0.2
HEOS 1/2	Hedgecock	18,532	6.1	0.1

The most general result apparent in Table 3 is that while the differences in parameters average out to small values, the standard deviations in these quarterly averaged differences are surprisingly large. More specifically, the average differences in field magnitude and components are typically about 0.2 gamma or less, although the standard deviations in these differences are typically about 0.6 gamma (magnitude) and 1.2 gammas (components). The origin of these relatively large standard deviations is not completely clear although most of the effect probably arises from the different locations of two spacecraft simultaneously measuring the IMF. (Recall that the solar wind convects the IMF past the Earth at about 230 Earth radii per hour, while typical separation distances of a pair of spacecraft making simultaneous IMF measurements is of the order of 30 Earth radii).

From Tables 3 and 4 it is apparent that long time scale averages of B_Z from most spacecraft are within 0.2 gamma of zero. However, IMP 1 and AIMP 2 deviate from this pattern. Possible errors in B_Z values should have only a second-order effect on long time scale averaged field magnitudes, but over periods when the IMF is predominantly northward of the ecliptic plane, the computed magnitudes will be somewhat smaller than the actual magnitudes. The reverse will be true for southward fields.

From Table 4, it is apparent that IMP 1 and IMP 3 have relatively small values of averaged field magnitude. Although some of this difference may be real, much of it results from the fact that the IMP 1 and IMP 3 hourly magnitudes were determined from 327-second magnitudes while hourly magnitudes for later spacecraft were determined from much finer time scale magnitudes. Schatten (1971) showed that long time averages of IMP 1 20-second magnitudes and 327-second magnitudes were different by about 0.6 gamma; this was probably caused by field directional fluctuations with periods between 20 and 327 seconds.

Tables 3 and 4 suggest a tendency for AIMP 1 field magnitudes to be a little high, relative to other spacecraft, by not more than 0.5 gamma.

The results of the mutual consistency study as applied to hourly standard deviations are as follows. Briefly, quarterly averages of hourly standard deviations in field components fell in the range 1.0 to 1.5 gammas while similar averages of the total field standard deviation (as defined in the preceding section of this report) fell in the range 2.5 to 3.0 gammas. There were no obviously noteworthy effects in the pairs-of-spacecraft comparisons.

The data are listed and plotted as provided by the experimenters, with these caveats to the user of this composite data set and with a spacecraft selection priority scheme determined accordingly (as previously discussed).

In summary, except for the IMP 1, IMP 3, and possibly AIMP 1 field magnitudes and the IMP 1 and AIMP 2 B_Z values and parameters computed therefrom, there is good mutual consistency among IMF parameters when compared on the basis of quarter-year averages. Field components and magnitudes are consistent typically to within 0.2 gamma, and computed angles are consistent typically to within 3 degrees. A better measure of the mutual consistency of individual hourly values however may be the rms standard deviation in the quarterly averages of the differences in hourly parameters. On this basis, we might say that field components and magnitudes are consistent typically to within 1.2 and 0.6 gammas, respectively, field latitude to within 15 degrees, and field longitude to within 25 degrees. Thus this composite data set should be useful for the study of long time scale averages and their variations and of variations in hourly averages when the hourly averages were all taken on the same spacecraft. However, a change in hourly values from one hour to the next when the two hours are represented by different spacecraft must be handled more cautiously than if both hours were represented by the same spacecraft. (Of 49,853 pairs of successive hours with data, only 657 pairs have data given by different spacecraft.) Similarly, correlation and spectral functions derived from this composite data set must be handled with care.

DATA PRESENTATION

In the following pages, the hourly averaged IMF data are listed and plotted. The listings include field magnitudes determined from fine time scale magnitudes, field direction angles in solar ecliptic coordinates determined from hourly averaged Cartesian components, field components normal to the ecliptic, the standard deviation parameter (discussed in detail earlier), and an identification of the spacecraft used for each hour. For each day's block of data, the date and the day-of-year are given above the block. Note that the convention that January 1 is day 1 is used, although on the tape from which the listings were generated and on the tapes supplied by the experimenters January 1 is day 0. Note also that where no data are available for a calendar day, no space is left for that day in the listings.

In the 27-day plots, field magnitude, direction angles, and the standard deviation parameter are plotted. The magnitude and standard deviation are plotted together, although the standard deviation relates to fluctuations in both the field magnitude and direction. Where the standard deviation exceeds the magnitude, the standard deviation is not plotted. This affects approximately 2 percent of the data (1185 hours). Note that the longitude plot covers 450 degrees. The bottom and top 45-degree intervals are used to try to reduce the number of times the trace would otherwise cross the full plot vertically due to small transient excursions of the field direction. Some solar rotations are not represented in the set of plots because there were no data for those rotations.

No spacecraft position information is listed or plotted in this report, but such information has been plotted for IMPs 4, 5, 6, and 7 and for AIMPs 1 and 2 in Behannon et al (1970) and in Fairfield et al (1973).
